

SETTLEMENT SPECIFICATION v2.3

1. Scope

This document defines how an authorized payment becomes a ledger entry. It covers capture, webhook handling and correction rows.

2. Capture

A capture request may settle less than the authorized amount but never more.

A capture above the authorized amount is rejected with 422.

Authorization expires after 7 days; a capture after that returns 422.

3. Idempotency

Every settlement carries the payment idempotency key.

The ledger enforces uniqueness on that key with a database constraint, not with an application-level check. See incident 2026-03-12.

4. Webhook handling

The PSP retries webhooks until it receives a 2xx. Retries are expected and are not an error condition. The worker must be safe to run twice.

5. Correction rows

The ledger is append-only. A wrong entry is corrected by appending a row with the opposite sign, never by updating or deleting the original.

The daily total must match after every correction batch.

6. Amounts

All amounts are integers in the smallest currency unit.

Floating point is not used anywhere in the settlement path.
